Current Efforts

- DC-3 Instrumentation
 - Field Mill
 - Instrumented static dischargers
 - Reelektonika DataGrabbers
- Rubidium Clock
 - Rubidium clock added to increase DataGrabber timing stability
 - GPS and LORAN files now time-synchronized
- Flight Testing
 - TMB July 2006
 - Thunderstorm and p-static noise

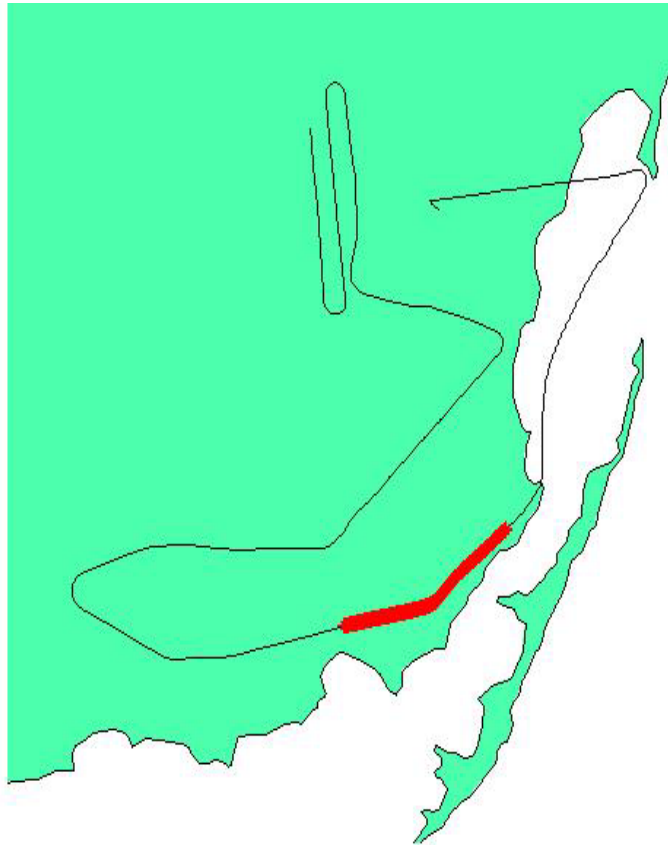

DC-3 Instrumentation

TMB Flight Test July 2006

- Why Tamiami?
 - Frequent, isolated t-storms
 - Comparison to July 2004 King Air data
 - Less cross-rate interference
- Flight test
 - Testing conducted over a two-week period
 - Ground data also collected
 - Stanford collected data during several flights

Conclusions (1 of 3)

- July 14 flight test provides baseline clear data
 - Tracking performance for both e-field and h-field antennas are almost identical
 - Differences in the e-field and h-field histograms can be attributed to the higher gain of the e-field antenna

Conclusions (2 of 3)

- Moderate-to-severe lightning was in the area for the July 18 flight
 - Effects are generally similar for both e-field and h-field antennas
 - Although tracking was not severely impacted, the h-field antenna clearly performs better than e-field antenna

Conclusions (3 of 3)

- Significant p-static conditions were encountered during the July 18 flight
 - Results showed that the h-field antenna is not significantly affected by aircraft charging
 - E-field tracking loss correlates well with periods of significant discharge activity
 - H-field tracking deficiencies are loosely correlated with severe aircraft discharges but tracking recovers quickly
